Fragmentation and shear band formation by slow compression of brittle porous media

Gergő Pál, Zoltán Jánosi, Ferenc Kus, and Ian G. Main

The authors report a numerical study of fragmentation of disordered granular porous media. They use discrete element simulation to study fragmentation in a shear band that occurs when a cylindrical sample is slowly compressed. Their results for the position, orientation, and width of the central shear band and the spatial and mass distributions of the fragments generally agree with experimental and field observations.

Rotationally induced fingering patterns in a two-dimensional heterogeneous porous medium
